

Nonlinear Model Predictive Control

Moritz Diehl

Dynamic Technical Processes

SMB process
(Dortmund)

Distillation column (Stuttgart)

Power Plant (Pavia)

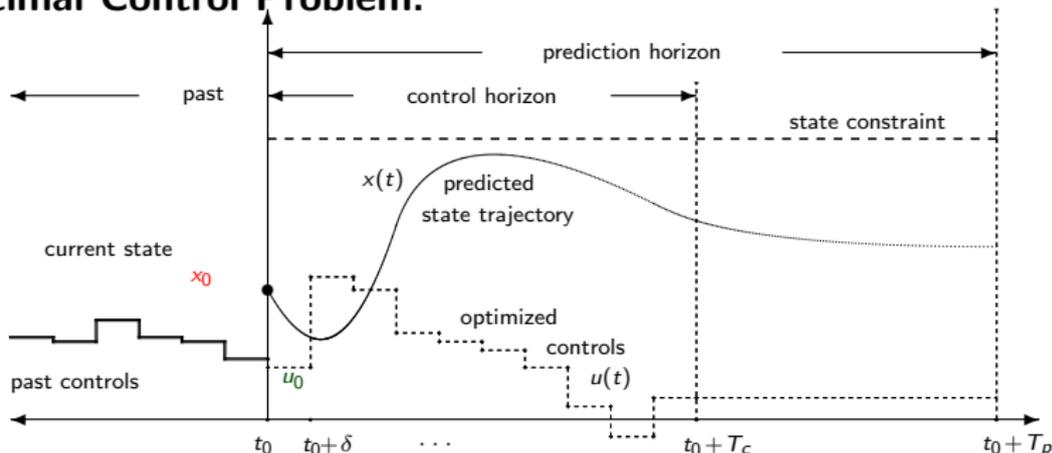

Polymer Reactor
(BASF)

- ▶ Idea: use model to optimally operate plants e.g. with respect to
 - ▶ productivity,
 - ▶ product purity,
 - ▶ energy consumption,
 - ▶ safety, ...
- ▶ Problem: offline optimal control cannot cope with model-plant mismatch and disturbances
- ▶ Need *closed loop* controls!

Nonlinear Model Predictive Control (NMPC)

- ▶ Each sampling time, solve for given system state x_0 an **Optimal Control Problem:**

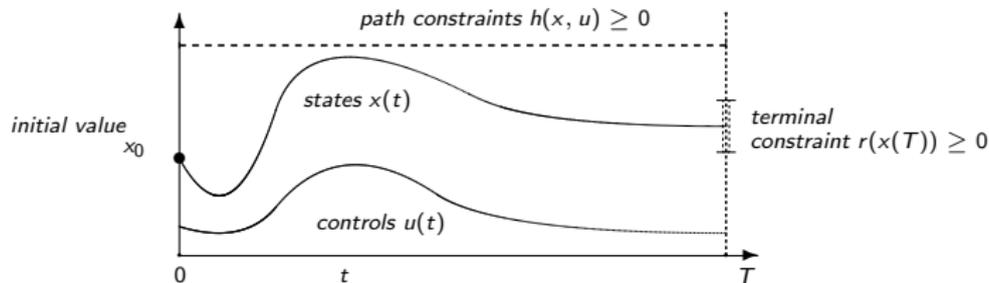

- ▶ Give first control move u_0 back to real-world system. Move horizon.
- ▶ Result: **Feedback law** $u_0(x_0)$. Can compensate for disturbances and modelling errors.

Example: Distillation Column (ISR, Stuttgart)

- ▶ Aim: to ensure product purity, keep two temperatures (T_{14} , T_{28}) constant despite disturbances
- ▶ least squares objective:
$$\min \int_{t_0}^{t_0+T_p} \left\| \begin{array}{c} T_{14}(t) - T_{14}^{\text{ref}} \\ T_{28}(t) - T_{28}^{\text{ref}} \end{array} \right\|_2^2 dt$$
- ▶ control horizon 10 min
- ▶ prediction horizon 10 h
- ▶ stiff DAE model with 82 differential and 122 algebraic state variables
- ▶ Desired sampling time: 30 seconds.

NMPC Optimal Control Problem

$$\text{minimize}_{x(\cdot), u(\cdot)} \int_0^T L(x(t), u(t)) dt + E(x(T))$$

$$\begin{aligned} \text{subject to} \quad & x(0) - x_0 = 0, && \text{(fixed initial value)} \\ & \dot{x}(t) - f(x(t), z(t), u(t)) = 0, \quad t \in [0, T], && \text{(DAE model)} \\ & g(x(t), z(t), u(t)) = 0, \quad t \in [0, T], \\ & h(x(t), z(t), u(t)) \geq 0, \quad t \in [0, T], && \text{(path constraints)} \\ & r(x(T)) \geq 0 && \text{(terminal constr.).} \end{aligned}$$

Online Optimization Algorithm

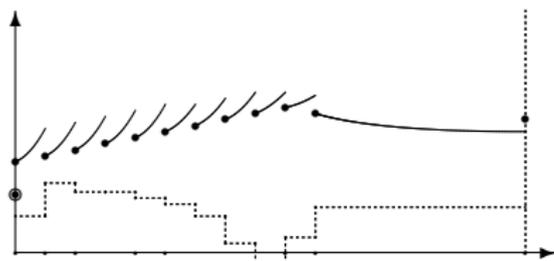

Basis:

- ▶ **Direct Multiple Shooting for DAE**

Online Features:

- ▶ Initialization of subsequent problems by **Initial Value Embedding**.
- ▶ **Real-Time Iterations** optimize while problem is changing.
- ▶ Proof of nominal stability of combined **System-Optimizer Dynamics**.

NLP in Direct Multiple Shooting

$$\underset{s, q}{\text{minimize}} \quad \sum_{i=0}^{N-1} l_i(s_i, q_i) + E(s_N)$$

subject to

$$s_0 - x_0 = 0, \quad (\text{initial value})$$

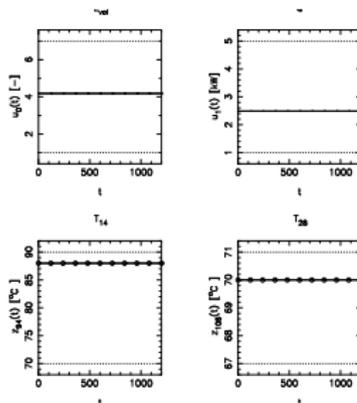

$$s_{i+1} - x_i(t_{i+1}; s_i, q_i) = 0, \quad i = 0, \dots, N-1, \quad (\text{continuity})$$

$$h(s_i, q_i) \geq 0, \quad i = 0, \dots, N, \quad (\text{discretized path constr.})$$

$$r(s_N) \geq 0. \quad (\text{terminal constraints})$$

Distillation Online Scenario

- ▶ System is in steady state, optimizer predicts constant trajectory:

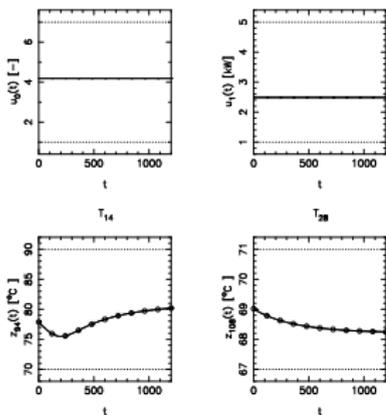

- ▶ **Suddenly**, system state x_0 is disturbed.
- ▶ What to do with optimizer?

Conventional Approach

- ▶ use offline method, e.g. MUSCOD-II with BFGS (Leineweber, 1999).
- ▶ initialize with **new** initial value x_0 and integrate system with **old** controls.
- ▶ iterate until convergence.

Initialization

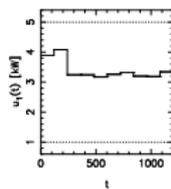

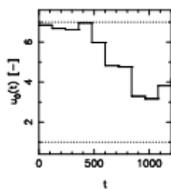

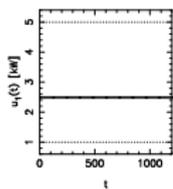

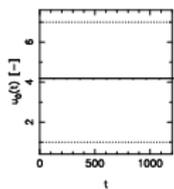

Conventional Approach

- ▶ use offline method, e.g. MUSCOD-II with BFGS (Leineweber, 1999).
- ▶ initialize with **new** initial value x_0 and integrate system with **old** controls.
- ▶ iterate until convergence.

Initialization

16th Iteration

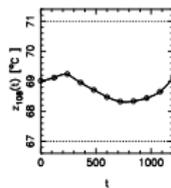

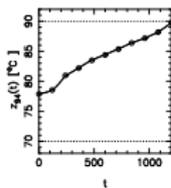

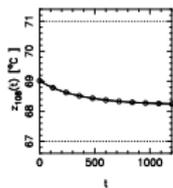

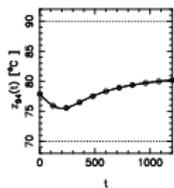

T_{14}

T_{28}

T_{14}

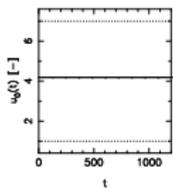

T_{28}

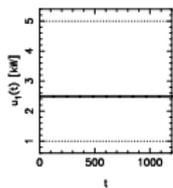

Conventional Approach

- ▶ use offline method, e.g. MUSCOD-II with BFGS (Leineweber, 1999).
- ▶ initialize with **new** initial value x_0 and integrate system with **old** controls.
- ▶ iterate until convergence.

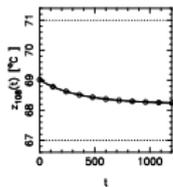

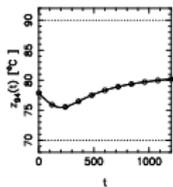

Initialization

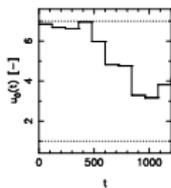

T_{14}

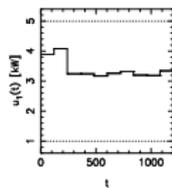

T_{28}

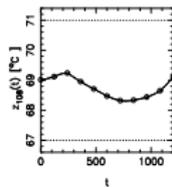

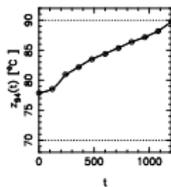

16th Iteration

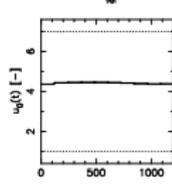

T_{14}

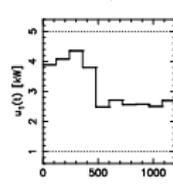

T_{28}

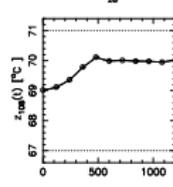

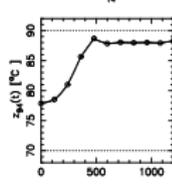

Solution (32nd Iteration)

T_{14}

T_{28}

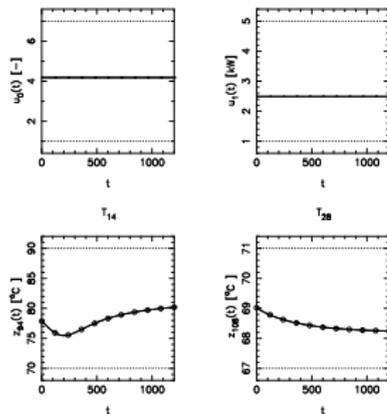

Solution only after 600 seconds - much too late!

Conventional, but with Gauss-Newton Hessian

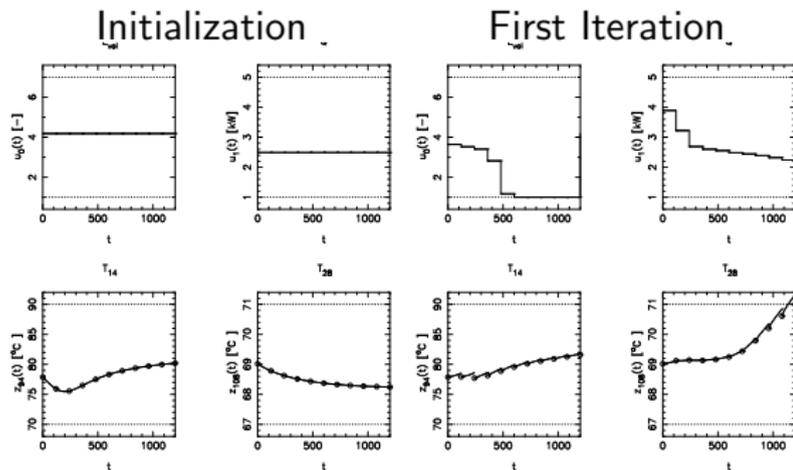

- ▶ use Gauss-Newton method for least-squares integrals (Diehl, 2001)

Initialization

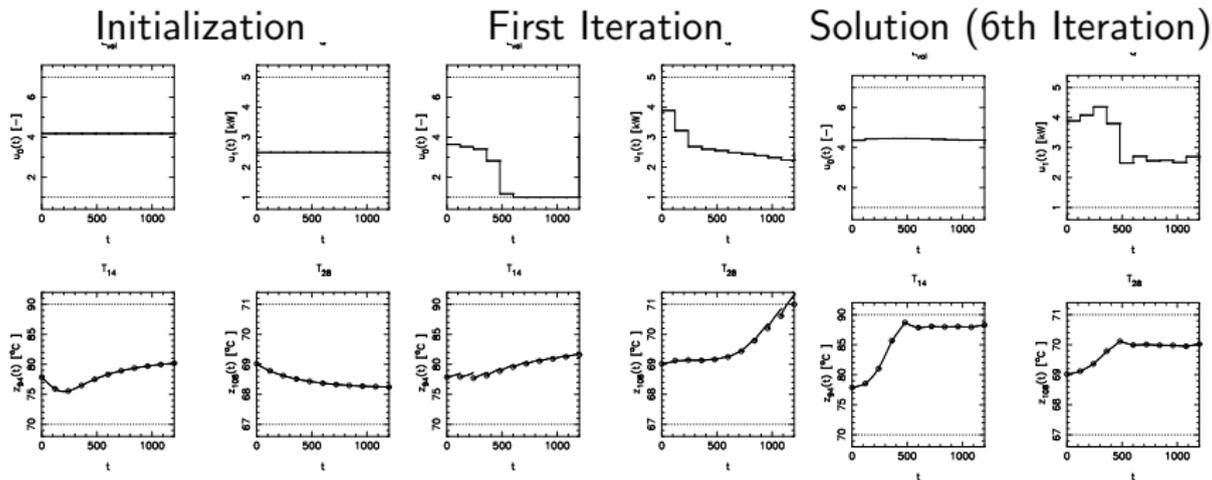

Conventional, but with Gauss-Newton Hessian

- ▶ use Gauss-Newton method for least-squares integrals (Diehl, 2001)

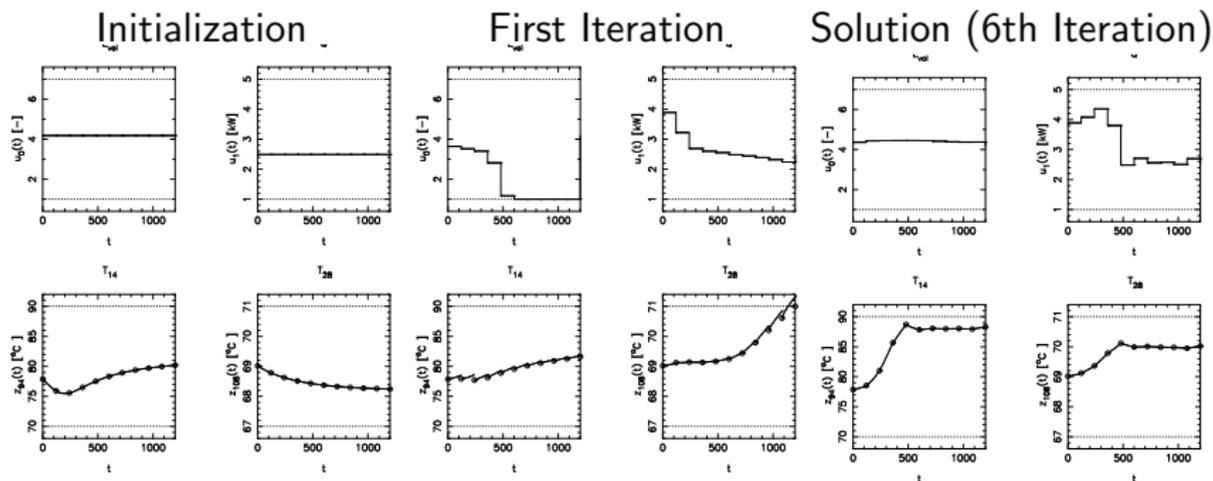

Conventional, but with Gauss-Newton Hessian

- ▶ use Gauss-Newton method for least-squares integrals (Diehl, 2001)

Conventional, but with Gauss-Newton Hessian

- ▶ use Gauss-Newton method for least-squares integrals (Diehl, 2001)

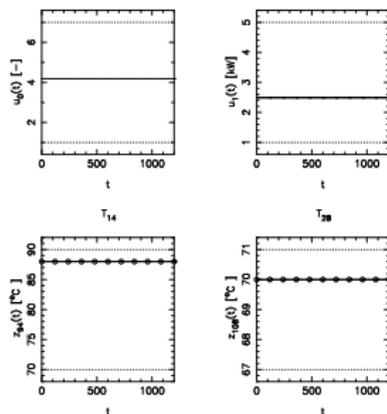

Solution still takes two minutes - can't we do better?

New Approach: Initial Value Embedding

- ▶ Initialize with **old** trajectory, accept violation of $s_0 - x_0 = 0$

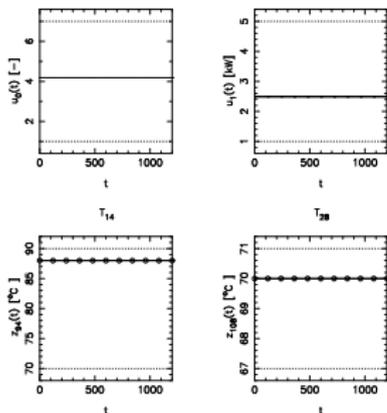

Initialization

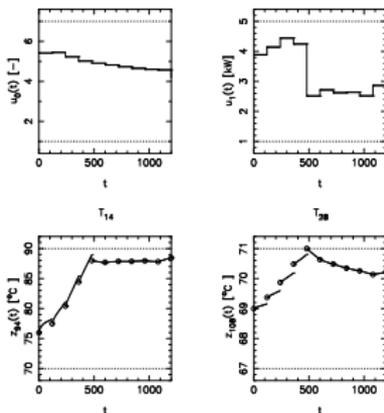

New Approach: Initial Value Embedding

- ▶ Initialize with **old** trajectory, accept violation of $s_0 - x_0 = 0$

Initialization

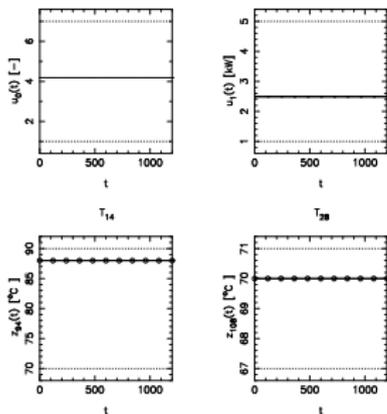

First Iteration

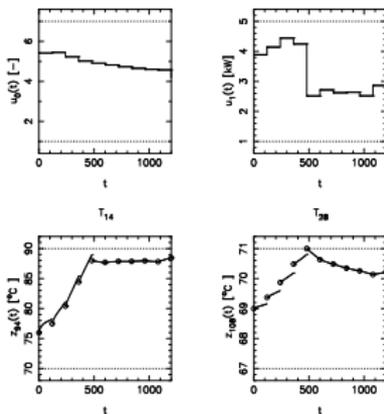

New Approach: Initial Value Embedding

- ▶ Initialize with **old** trajectory, accept violation of $s_0 - x_0 = 0$

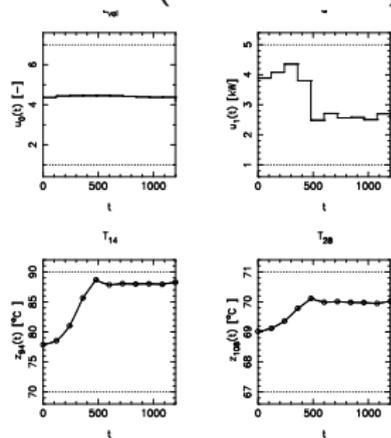

Initialization

First Iteration

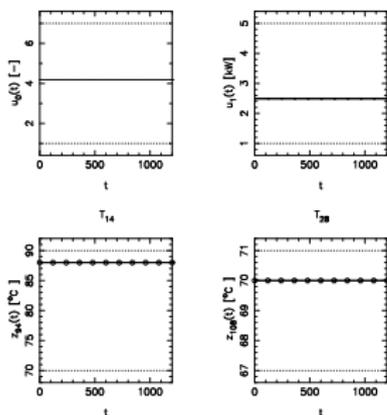

Solution (3rd Iteration)

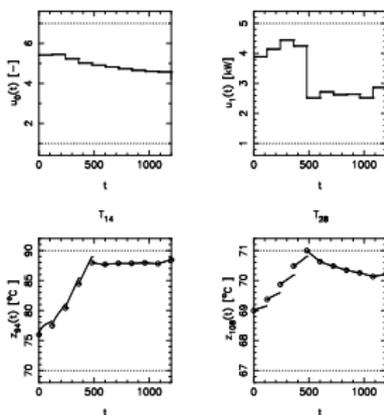

New Approach: Initial Value Embedding

- ▶ Initialize with **old** trajectory, accept violation of $s_0 - x_0 = 0$

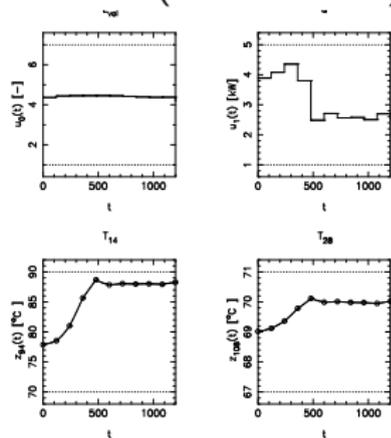

Initialization

First Iteration

Solution (3rd Iteration)

First iteration nearly solution! Is this always so?

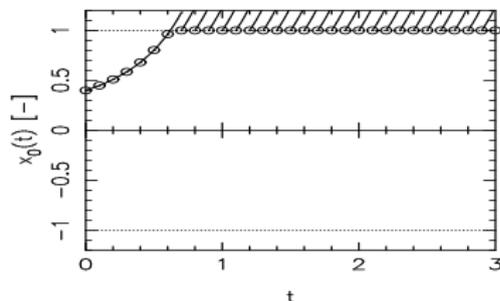

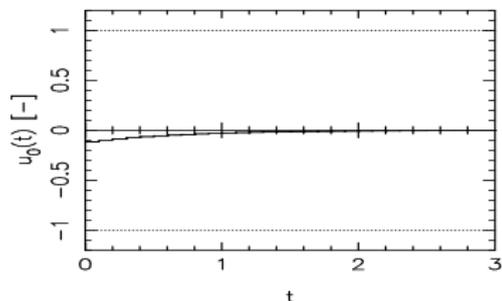

Test with NMPC Example Problem

$$\begin{aligned} \text{minimize} \quad & \int_0^3 x(t)^2 + u(t)^2 dt \\ \text{s.t.} \quad & \begin{cases} x(0) = x_0, \\ \dot{x} = (1+x)x + u, & t \in [0, 3], \\ |x| \leq 1, |u| \leq 1, & t \in [0, 3], \\ x(3) = 0. \end{cases} \end{aligned}$$

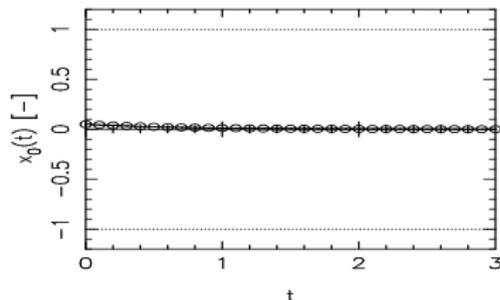

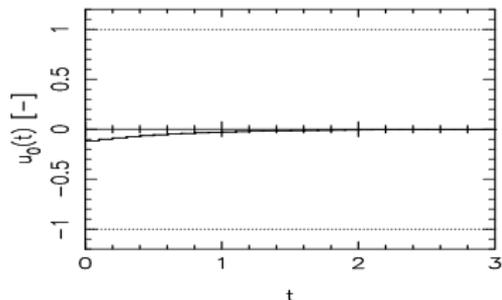

- ▶ Before, system was in state $x_0 = 0.05$
- ▶ Optimizer had found solution for $x_0 = 0.05$
- ▶ After disturbance, new state is $x_0 = 0.40 \gg 0.05$
- ▶ How to compute new solution?

Transition from $x_0 = 0.05$ to $x_0 = 0.4$

Conventional Initialization (old controls, new initial value):

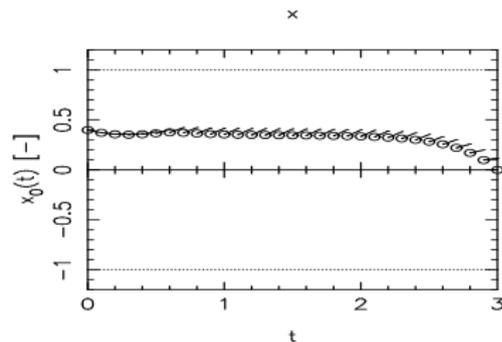

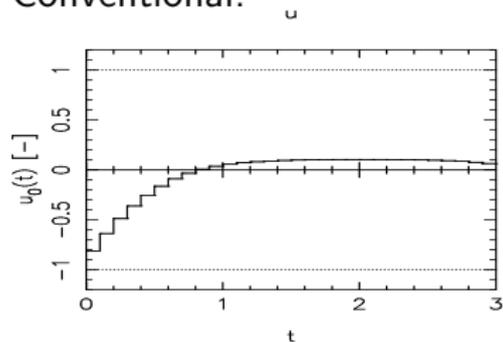

Initial Value Embedding (old solution, violates $s_0 - x_0 = 0$):

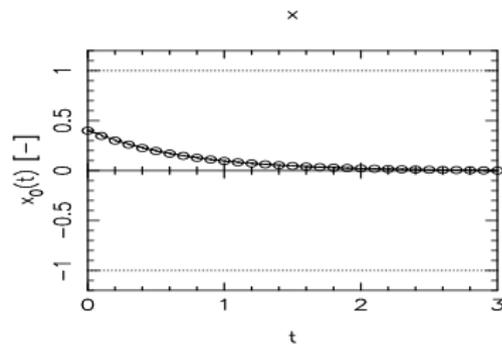

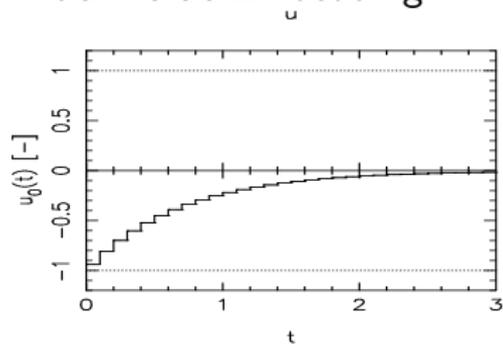

First Iteration

Conventional:

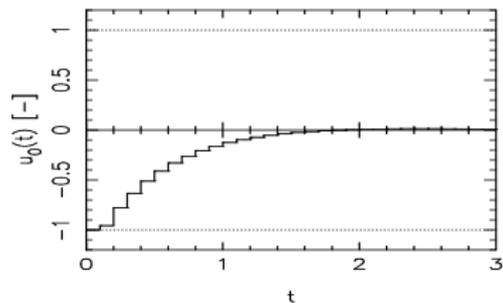

Initial Value Embedding:

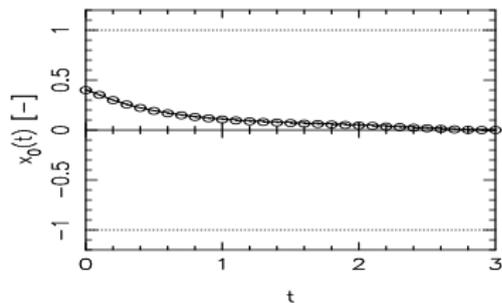

2nd Iteration

Conventional: u

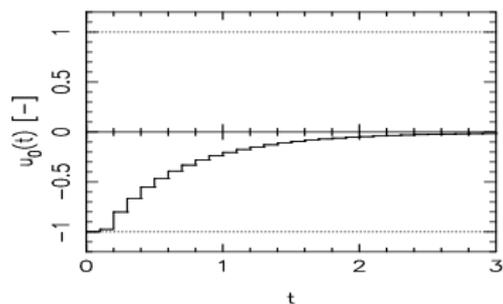

x

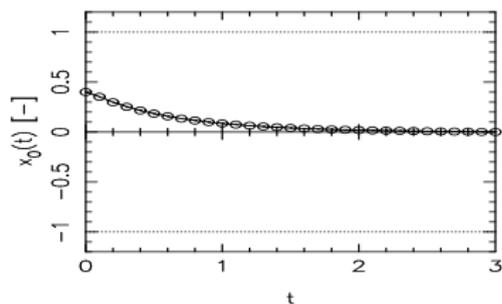

Initial Value Embedding (already solution):

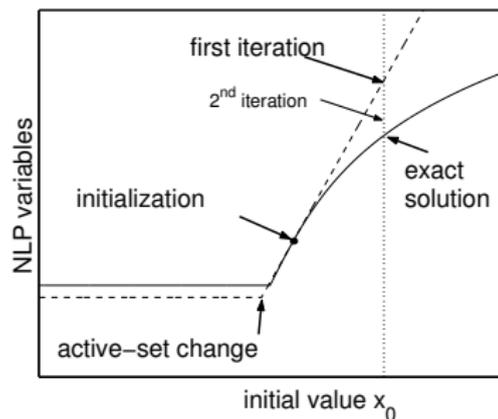

u

x

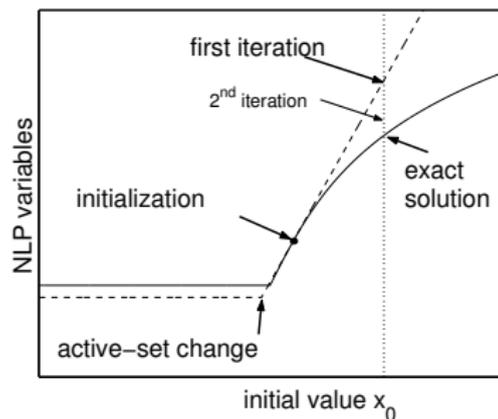

Initial Value Embedding

- ▶ first iteration is tangential predictor for exact solution (for exact Hessian SQP)
- ▶ also valid for active set changes
- ▶ derivative can be computed *before* x_0 is known: first iteration nearly without delay

Initial Value Embedding

- ▶ first iteration is tangential predictor for exact solution (for exact Hessian SQP)
- ▶ also valid for active set changes
- ▶ derivative can be computed *before* x_0 is known: first iteration nearly without delay

Why wait until convergence and do nothing in the meantime?

Real-Time Iteration Algorithm:

1. **Preparation Step (long):**

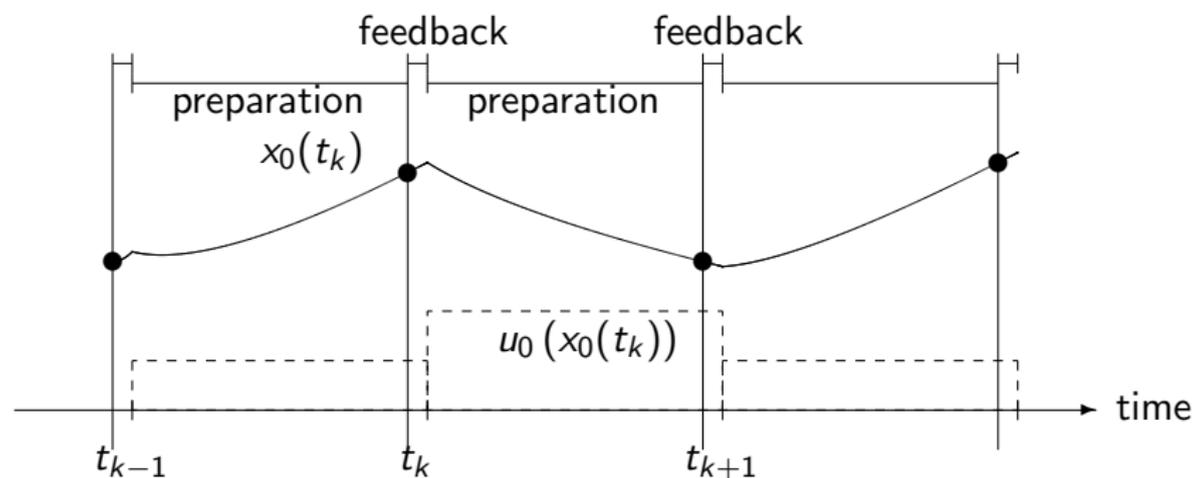

Linearize system at current iterate, perform partial reduction and condensing of quadratic program.

2. **Feedback Step (short):**

When new x_0 is known, solve condensed QP and implement control u_0 immediately. Complete SQP iteration. Go to 1.

- ▶ minimal cycle-duration (as **one** SQP iteration)
- ▶ negligible feedback delay (≈ 1 % of cycle)
- ▶ nevertheless fully nonlinear optimization

Real-time iterations minimize feedback delay

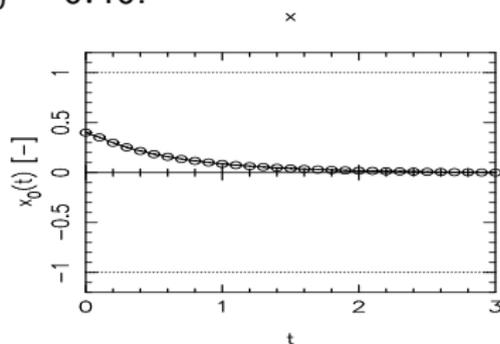

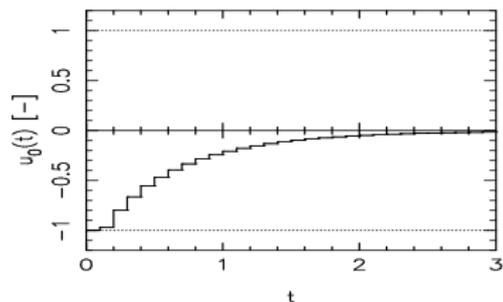

For distillation model:

- ▶ preparation time: ≈ 20.0 seconds
- ▶ feedback delay: ≈ 0.2 seconds ($\approx 1\%$)

Real-Time Iterations with NMPC Example

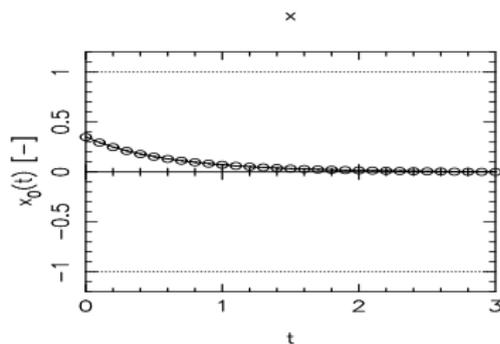

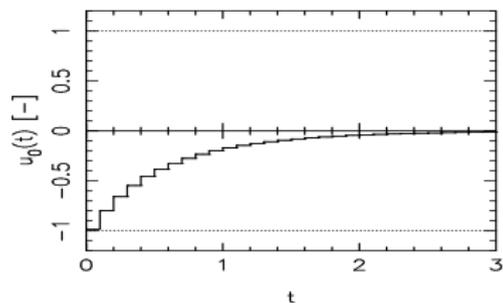

- ▶ go through initial values $x_0 = 0.40, 0.35, \dots, 0.05$,
- ▶ then jump to $-0.50, -0.55, \dots, -0.70$

- ▶ Start with exact solution of $x_0 = 0.40$:

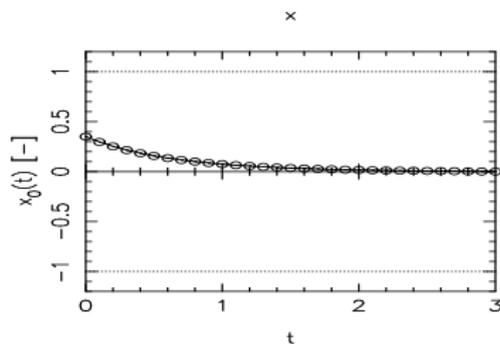

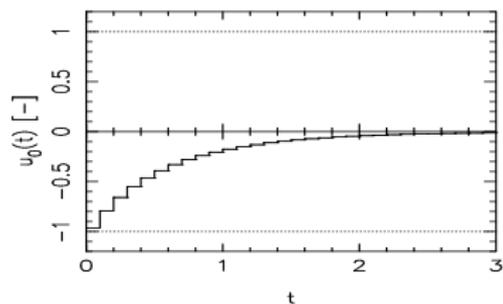

1st Real-Time Iteration, $x_0 = 0.35$

Real-time iterations:

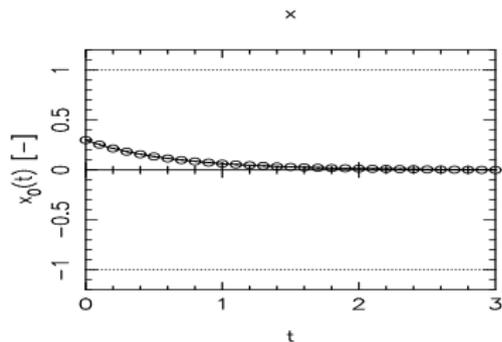

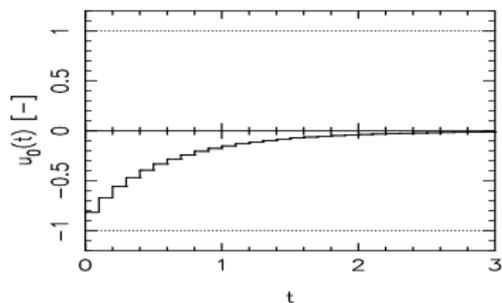

Exact solution for comparison:

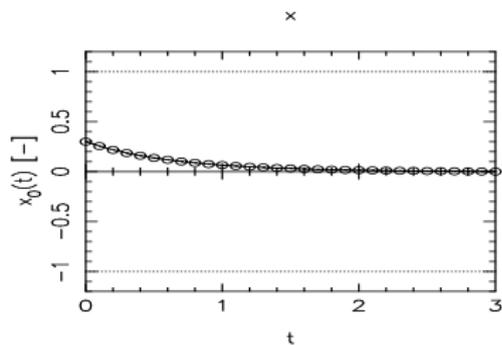

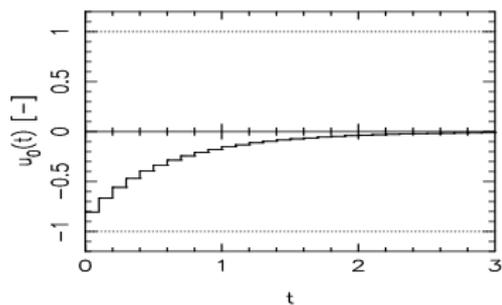

2nd Real-Time Iteration, $x_0 = 0.30$

Real-time iterations:

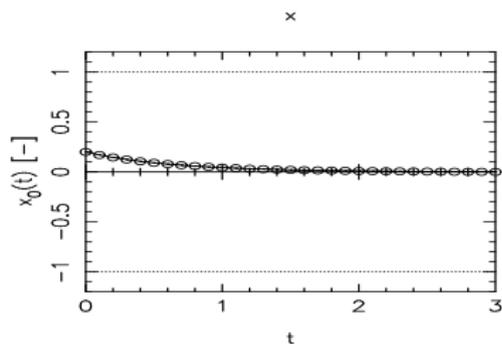

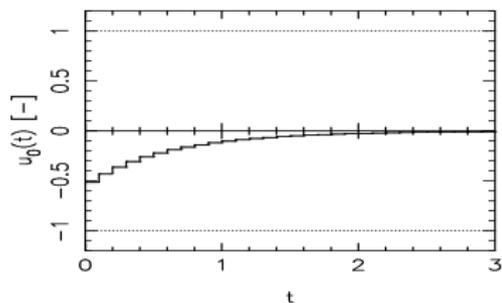

Exact solution for comparison:

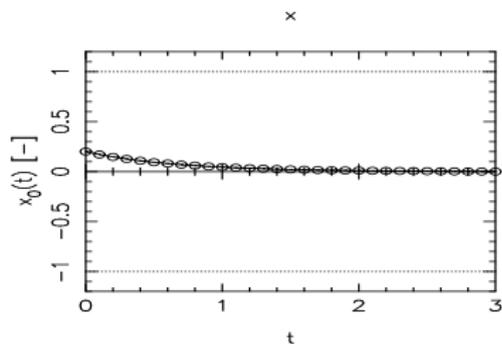

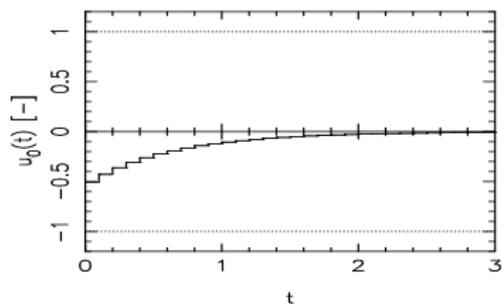

4th Real-Time Iteration, $x_0 = 0.20$

Real-time iterations:

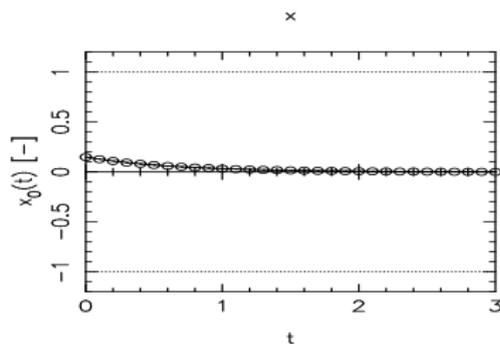

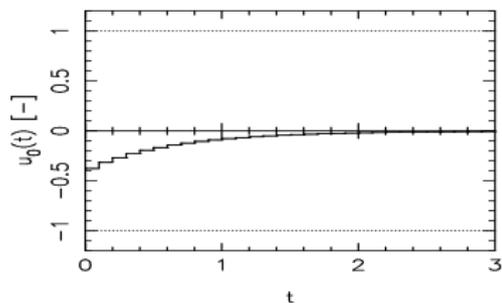

Exact solution for comparison:

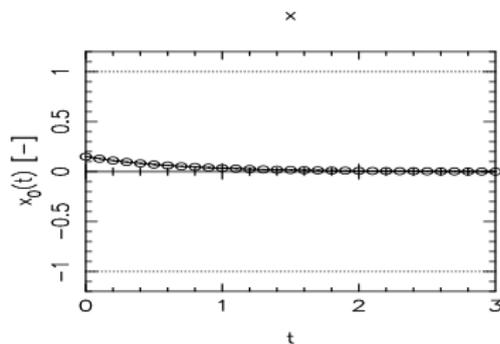

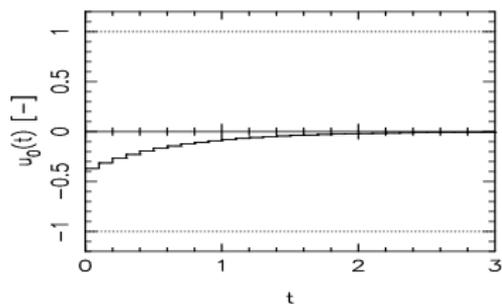

5th Real-Time Iteration, $x_0 = 0.15$

Real-time iterations:

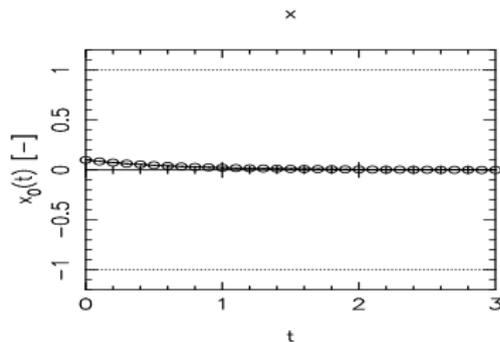

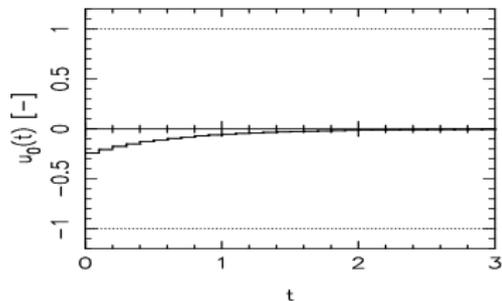

Exact solution for comparison:

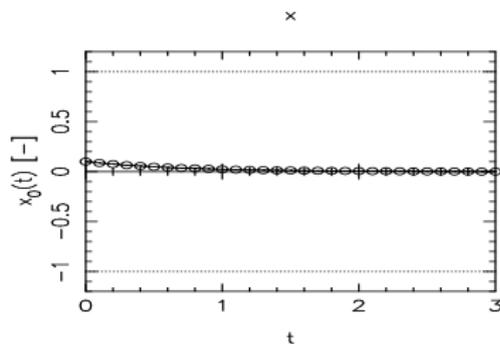

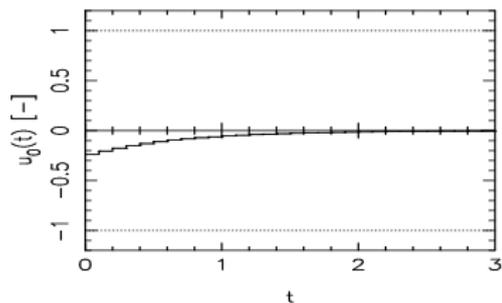

6th Real-Time Iteration, $x_0 = 0.10$

Real-time iterations:

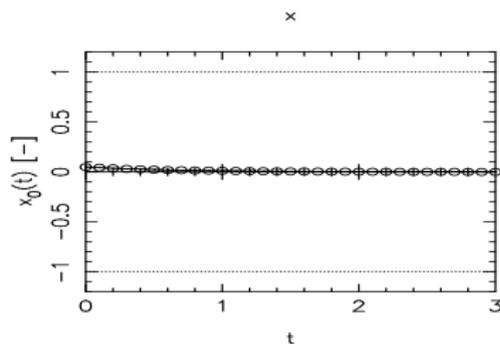

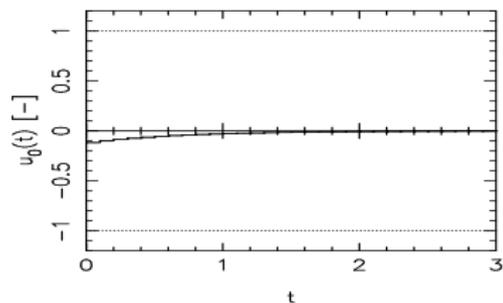

Exact solution for comparison:

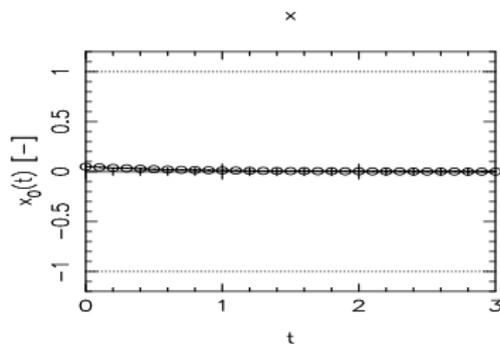

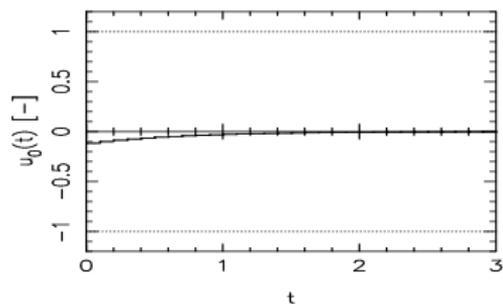

7th Real-Time Iteration, $x_0 = 0.05$

Real-time iterations:

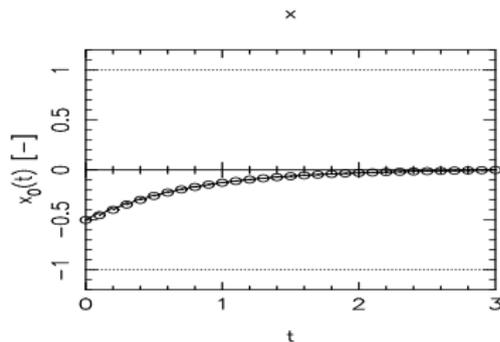

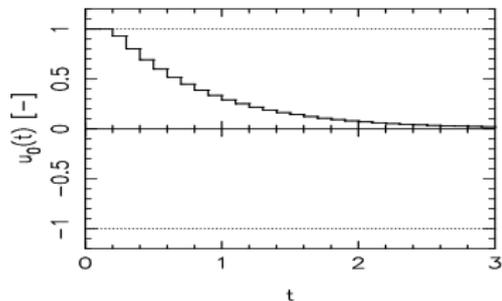

Exact solution for comparison:

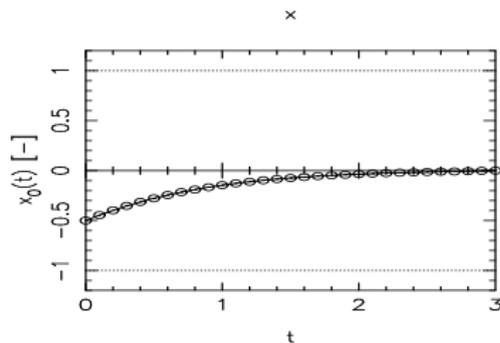

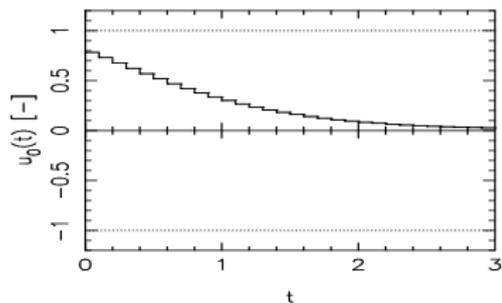

8th Real-Time Iteration, $x_0 = -0.50$

Real-time iterations:

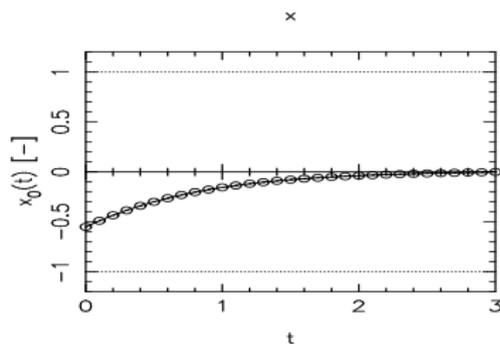

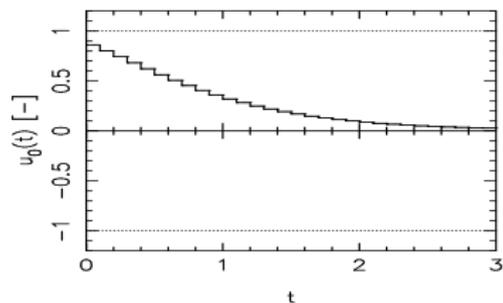

Exact solution for comparison:

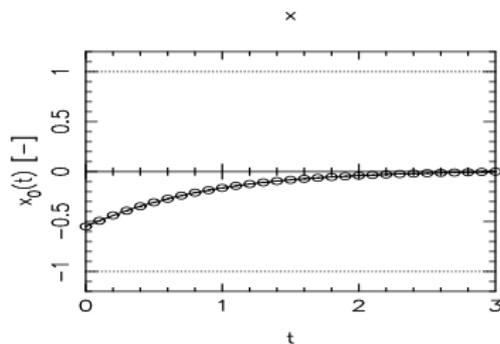

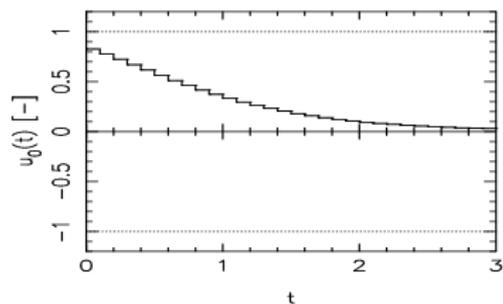

Next Real-Time Iteration, $x_0 = -0.55$

Real-time iterations:

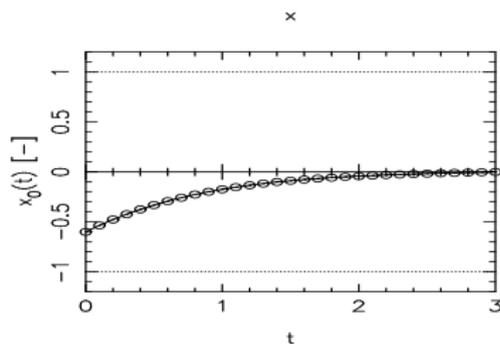

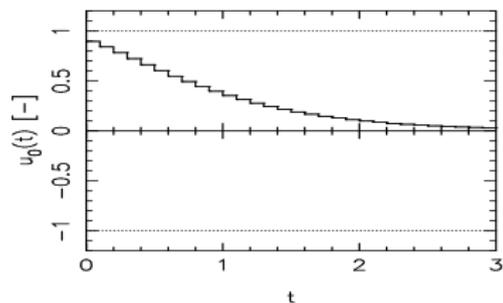

Exact solution for comparison:

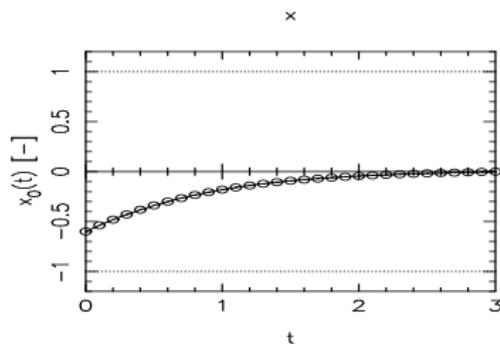

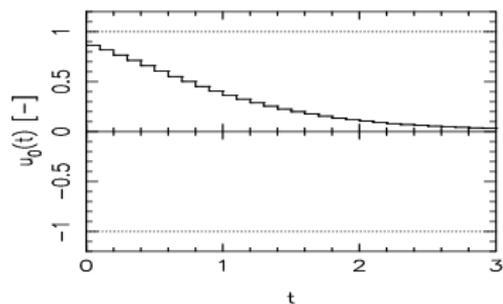

Next Real-Time Iteration, $x_0 = -0.60$

Real-time iterations:

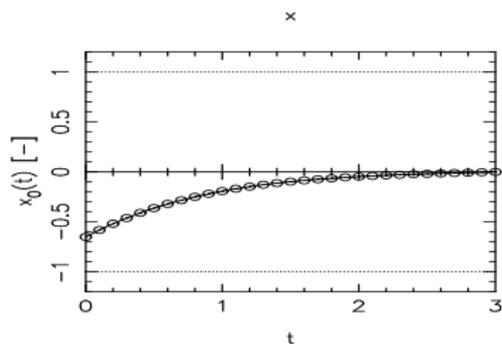

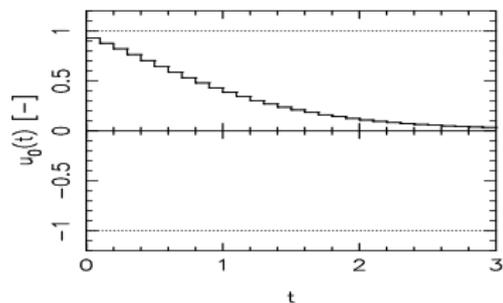

Exact solution for comparison:

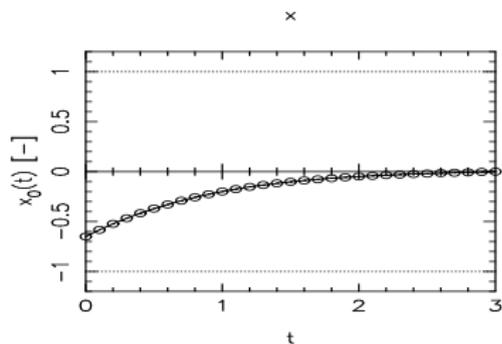

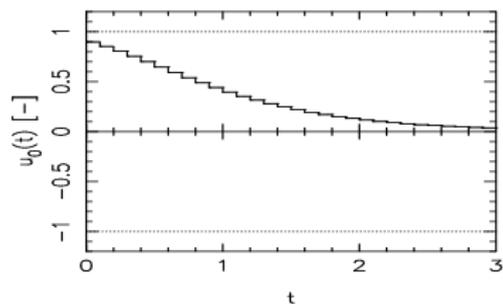

Next Real-Time Iteration, $x_0 = -0.65$

Real-time iterations:

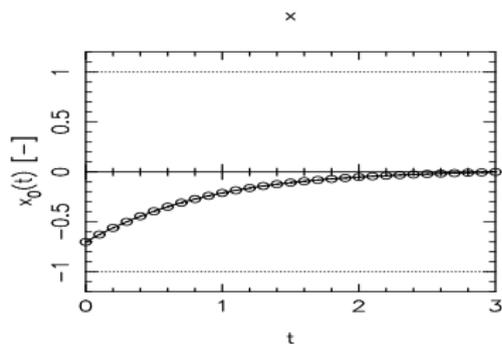

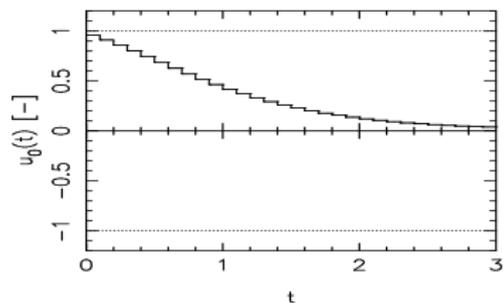

Exact solution for comparison:

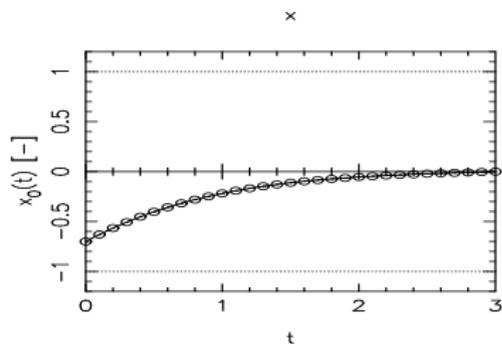

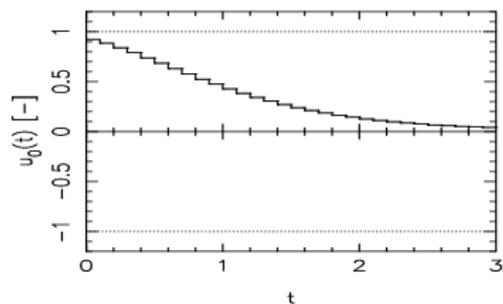

Next Real-Time Iteration, $x_0 = -0.70$

Real-time iterations:

Exact solution for comparison:

Nominal Stability of Closed Loop?

- ▶ Real process and optimizer are coupled with each other. Can numerical errors grow and destabilize closed loop?
- ▶ Stability analysis combines concepts from both, **NMPC stability theory** and **convergence theory of nonlinear optimization**.
- ▶ Nominal stability shown under realistic assumptions.
[Diehl, Findeisen, Bock, Schlöder, Allgöwer: Nominal stability of the real-time iteration scheme for nonlinear model predictive control. IEE Control Theory Appl. (2005)]
- ▶ After disturbance of size ϵ : loss of optimality is of order $O(\epsilon^2)$ for Gauss-Newton, and $O(\epsilon^4)$ for exact Hessian.

[Diehl, Bock, Schlöder: A Real-Time Iteration Scheme for Nonlinear Optimization in Optimal Feedback Control. SIAM J. Control & Opt. (2005)]

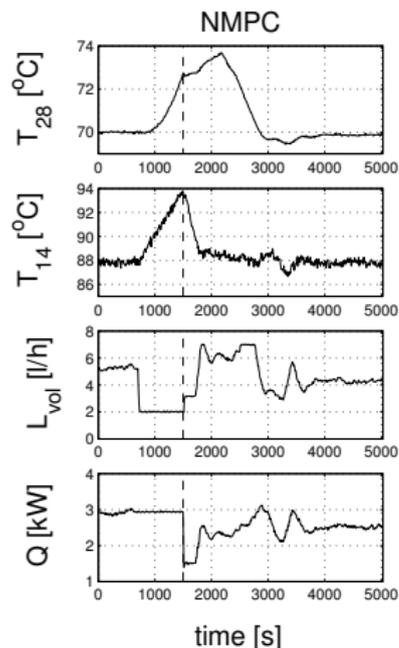

Realization at Distillation Column

(with Allgöwer, Findeisen, Nagy, Schwarzkopf, Uslu)

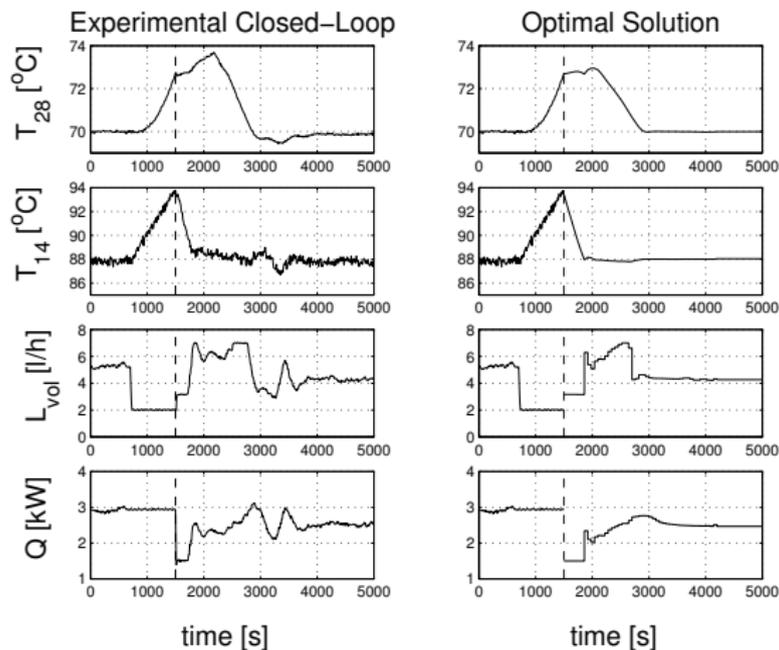

- ▶ Parameter estimation using dynamic experiments
- ▶ Online state estimation with Extended Kalman Filter variant, using only 3 temperature measurements to infer all 82 system states
- ▶ Implementation of estimator and optimizer on Linux Workstation.
- ▶ Communication with Process Control System via FTP all 10 seconds.
- ▶ Self-synchronizing processes.

Large Disturbance (Heating), then NMPC

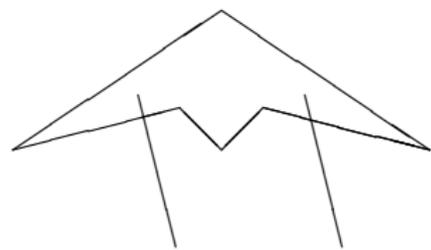

- ▶ Overheating by manual control
- ▶ NMPC only starts at $t = 1500$ s
- ▶ PI-controller not implementable, as disturbance too large (valve saturation)
- ▶ NMPC: at start control bound active
⇒ T_{28} rises further
- ▶ Disturbance attenuated after half an hour

Comparison with Theoretical Optimal Solution

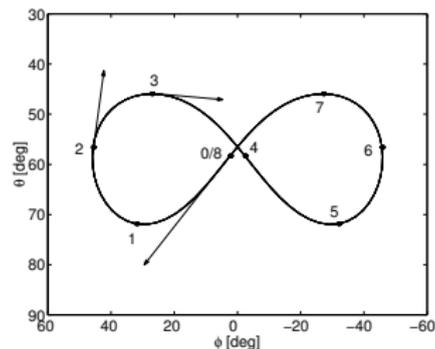

Simulated Control of a Looping Kite

Kite can be controlled by two lines:

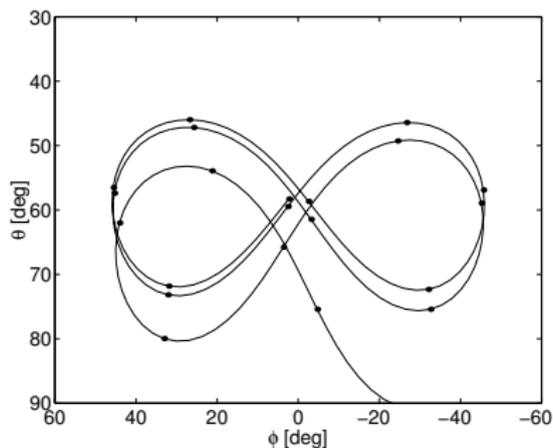

Control aim is to fly a “lying eight”:

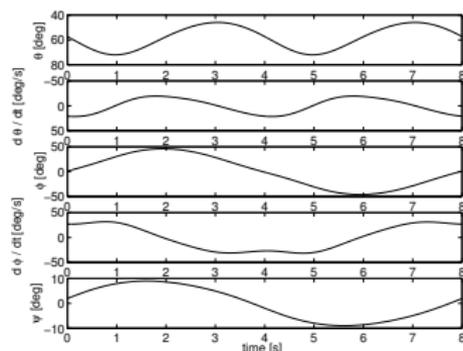

Period duration: 8 seconds

Orbit is Open Loop Unstable

Simulated open loop controlled kite crashes onto ground after 25 seconds!
 \Rightarrow feedback necessary

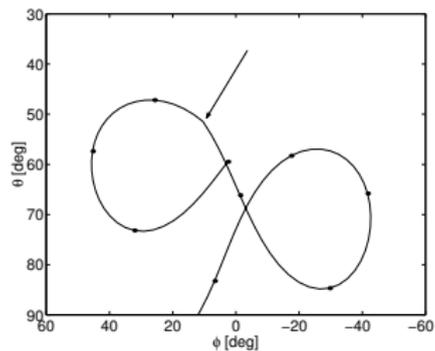

Nonlinear Model Predictive Control Setup

- ▶ predict two full periods (16 seconds)
- ▶ optimize quadratic deviation from “lying eight”
- ▶ choose one second sampling time
- ▶ use real-time iterations
recall: negligible feedback delay

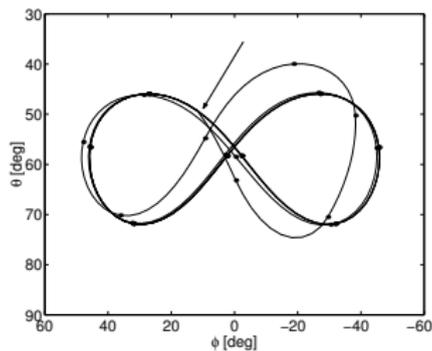

Weak Kick

Open loop controlled system:

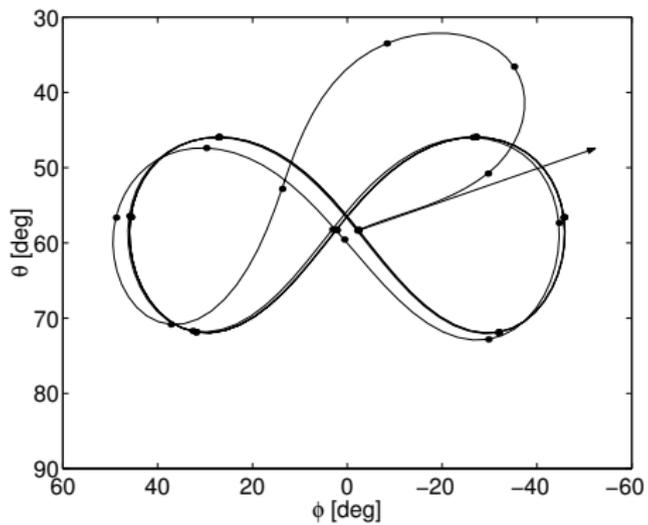

Crash after 5 seconds

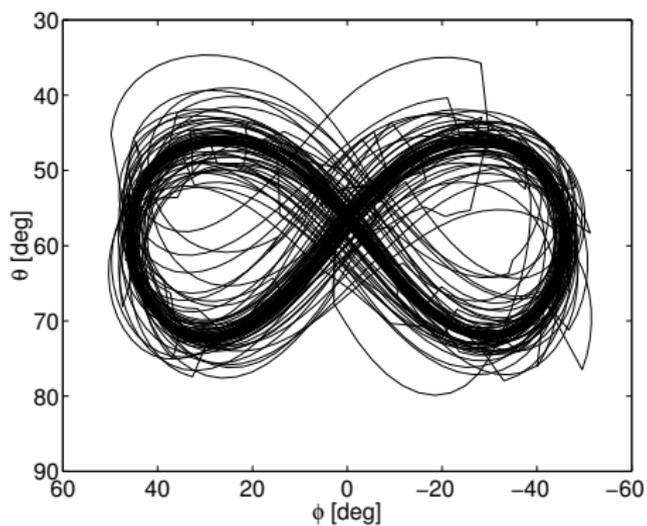

NMPC controlled system:

Strong Kick

Robustness Test with Strong Random Kicks

Summary

- ▶ **Nonlinear Model Predictive Control (NMPC)** allows optimal control of real world processes. Requires online optimization.
- ▶ Online optimization by no means just an application of fast offline optimization methods!
- ▶ **Direct, simultaneous** optimal control algorithms favourable for NMPC.
- ▶ Our algorithm based on:
 - ▶ **direct multiple shooting** with **Gauss-Newton** algorithm
 - ▶ **initial value embedding** to deliver tangential predictor
 - ▶ **real-time iterations** to have minimal cycle times and negligible feedback delay
- ▶ Nominal stability can be guaranteed.
- ▶ Thouroughly tested numerically and experimentally.
